

Statement of Linda Capuano
Administrator
U.S. Energy Information Administration
U.S. Department of Energy
Before the
Energy and Water Development Appropriations Subcommittee
United States House of Representatives
February 7, 2019

Chairwoman Kaptur, Ranking Member Simpson, Members of the Committee, I appreciate the opportunity to appear before you today to provide testimony on U.S. energy trends.

This is a transformational time for the United States energy industry. After decades of the United States importing more energy than it exports, EIA now forecasts that our country will become a net energy exporter in 2020 (Figure 1). The crossover to being a net exporter occurs as crude oil production continues to increase. The United States produced almost 11 million barrels per day (b/d) of crude oil in 2018, exceeding our previous 1970 record of 9.6 million barrels per day. EIA expects that U.S. crude oil production will continue remain greater than 14.0 million b/d through 2040.

Figure 1. U.S. energy imports and exports, 1949-2050

Source: U.S. Energy Information Administration, *Monthly Energy Review and Annual Energy Outlook 2019*

The U.S. oil and natural gas industry—which consists of natural gas, crude oil, and other liquids production—has seen impressive growth as hydraulic fracturing and horizontal drilling have led to economically competitive development of shale resources that were previously uneconomical to develop (Figure 2). Nearly all of the growth in U.S. crude oil production in 2018

came from tight oil formations, and tight oil production accounted for 58% of total crude oil production in 2018 compared with 53% in 2017. In comparison, tight oil production accounted for less than 7% of total U.S. crude oil output as recently as in 2000.

Figure 2. U.S. liquid fuels production reached historically high levels

Source: U.S. Energy Information Administration, *Monthly Energy Review and Annual Energy Outlook 2019*

The United States became the world’s largest producer of crude oil in 2018, surpassing Saudi Arabia and Russia. Our natural gas plant liquids (NGPL) production, a component of all liquid fuels production, set an all-time high of 4.4 million b/d in 2018. The combined increases in crude oil and NGPL output, coupled with our sophisticated and plentiful refining capacity, have led the United States to become a major exporter of crude oil and petroleum products. By the fourth quarter of 2020, EIA expects exports of crude oil and petroleum products from the United States to exceed imports by an average of 0.9 million b/d. In sharp contrast, the United States imported 6.2 million b/d more crude oil and petroleum products than it exported in 2013.

However, although imports have declined, the United States will continue to import crude oil, particularly heavy and medium crude oil to meet the specific needs of many U.S. refiners. An increasing share of United States crude oil production is expected to be light and sweet oil, but many refineries, such as those on the Gulf Coast, are optimized to process heavy crude oil grades.

In addition to configurational mismatches between production and refining, transportation constraints will also continue to lead refiners to rely on crude oil imports to meet refining capacity. For example, insufficient infrastructure exists to move sufficient crude oil production supply from the Gulf region to meet domestic refinery demand on the East and West Coasts. This robust import-export trade indicates the United States is emerging as a globally significant *merchant refiner*.

Similar developments in domestic shale natural gas resources have enabled the United States to become a net exporter of natural gas. In 2017, total natural gas exports from the United States exceeded imports for the first time since the 1950s. In 2017, U.S. natural gas production exceeded consumption for the first time since 1966 (Figure 3). Since then, U.S. natural gas production has reached a record high of 30 trillion cubic feet (Tcf) in 2018. We expect these trends to continue. As a result, net U.S. natural gas exports will continue to grow as liquefied natural gas (LNG) and pipeline exports increase.

Figure 3. Natural gas production continues to exceed consumption

Abundant, domestic natural gas production and the resulting relatively low natural gas prices have led to other changes in the U.S. energy landscape. Despite relatively flat demand for electricity in the United States during the past decade, natural gas and renewables displaced less economically competitive sources of electric power generation, and natural gas became the largest share of electric power generation in 2016 (Figure 4).

Figure 4. Natural gas is the dominant fuel for electric power generation

Technological advances and supporting policies in the production of energy in the United States have also enabled gains in U.S. wind and solar capacity and generation, which have been growing consistently and reached all-time highs in 2018. According to our just-released *Annual Energy Outlook 2019* (AEO2019), under current policies and regulations, EIA's Reference case projects that generation from all renewable sources will surpass nuclear in 2020 and coal after 2025. Most of the growth in renewable generation has come from wind and solar energy. As a result of renewables growth, EIA projects that after 2020, carbon dioxide (CO₂) emissions will remain at least 2% lower than the 2020 level through 2050.

Short-term energy trend highlights

Energy commodity prices saw annual increases in 2018 compared with 2017; however, commodity prices ended 2018 lower than they began the year

Crude oil prices had been increasing for most of 2018 in response to the increased potential for supply constraints and declining global petroleum inventories throughout much of 2017. The potential supply constraints include the declining Iranian exports as a result of U.S. sanctions targeting its oil sector; declining production in Venezuela; and periodic disruptions from other producers, including Libya and Nigeria.

Brent crude oil reached a four-year high of \$86 per barrel (b) on October 4, 2018. However, several factors contributed to the subsequent sharp fall in crude oil prices. Crude oil production in the United States, Russia, and Saudi Arabia increased to or near record highs. Concerns about slowing global economic growth and its impact on oil demand also contributed to recent declines in crude oil prices. Waivers granted to certain countries that import Iranian crude oil also helped to ease concerns about crude oil availability in the near term. Crude oil prices ended 2018 lower than where they started at the beginning of the year for the first time since 2015.

The West Texas Intermediate (WTI) crude oil prices ended 2018 lower than \$50/b despite having increased to almost \$71/b in July 2018, the highest average monthly price for WTI since late 2014. Prices have remained at about \$50/b so far in 2019.

EIA expects that, in the short term, similar market trends will continue to prevail as global oil production is expected to exceed global consumption in 2019 and 2020; however, the global market is expected to become more balanced in 2019 and 2020 (Figure 5).

Figure 5. Oil supply growth continues to slightly outpace consumption growth in 2019 and 2020

Source: Short-Term Energy Outlook, January 2019

Henry Hub natural gas prices remained lower than an average of \$3.00 per million British thermal units (MMBtu) in seven months in 2018 and an average of \$3.15 per MMBtu for the year. Spot natural gas prices remained lower than \$3.00 per MMBtu for much of the year as domestic production reached new record highs, which more than offset the effects of record levels of consumption and exports (Figure 3).

EIA estimates that coal production fell by about 20 million short tons (MMst) in 2018, despite a 19 MMst increase in coal exports. Average coal prices were \$2.07 per MMBtu in 2018 and are expected to remain at about that level in 2019 and 2020. Low natural gas prices have primarily contributed to reduced demand for coal in the United States, with coal accounting for 28% of total U.S. electricity generation in 2018, compared with 45% in 2010. Natural gas accounted for 35% of total U.S. electricity generation, compared with 24% in 2010.

Residential sector retail electricity prices averaged 12.9 cents/kilowatthour in 2018, and prices are expected to rise to 13.3 cents/kilowatthour in 2019. Similarly, industrial and commercial electricity prices are expected to rise in 2019.

Among renewable sources, hydroelectricity continued to provide the most electricity generation in 2018, with wind generation trailing only slightly behind that of hydroelectricity. EIA expects that wind generation will exceed that of hydroelectricity in 2019. Overall, renewable generation provided 17% of total U.S. electricity generation in 2018.

Long-term energy trend highlights

EIA's *Annual Energy Outlook 2019* (AEO2019), released on January 24, 2019, projects that the United States will become a net energy exporter in 2020 and is projected to remain so through 2050 as a result of large production increases in crude oil, natural gas, and natural gas plant liquids (NGPL) coupled with slower growth in U.S. energy consumption.

The United States produced 10.9 million barrels per day (b/d) of crude oil in 2018, passing the 10 million b/d mark for the first time and surpassing the previous record of 9.6 million b/d set in 1970, according to the *Short-Term Energy Outlook*, January 2019. The growth in liquid fuels production is projected to continue through 2050. In the short term, EIA also forecasts the United States to be a net exporter of petroleum in the fourth quarter of 2020, with liquid fuel net exports exceeding crude oil net exports by nearly 0.9 million b/d.

Similarly, natural gas production reached an all-time high in 2018. Production of natural gas and NGPL is expected to have the highest growth of all fossil fuels and account for nearly one-third of U.S. liquids production through 2050. Natural gas prices are projected to remain comparatively low through 2050, leading to increased use of natural gas across end-use sectors as well as increasing LNG exports.

The electric power sector is projected to see a notable shift in fuel mix. Growth in solar, wind, and natural gas-fired electricity generation is projected to be accompanied by additional retirements of coal and nuclear power plants. As a result of this changing fuel mix, the electric power sector is projected to see a steady decrease in carbon dioxide (CO₂) intensity after 2030. Carbon dioxide intensity refers to CO₂ emissions per unit of energy output in British thermal units.

Total energy

The United States becomes a net energy exporter in 2020

The United States is projected to become a net energy exporter in 2020 in the AEO2019 Reference case for the first time since the 1950s. The projected changes are driven mostly by evolving trade flows of liquid fuels and natural gas. The United States will remain a net energy exporter through 2050, as increases in domestic crude oil, natural gas, and natural gas plant liquids production continue to outpace growth in domestic consumption of petroleum products.

EIA projects that energy exports will exceed imports until the 2040s, when falling domestic crude oil production leads to a decrease in exports, and a growing U.S. economy and higher domestic gasoline consumption leads to an increase in imports.

Although the United States is expected to become a net energy exporter, heavy and medium crude oil will continue to be imported through the projection period to meet the needs of many U.S. refiners. Much of the United States' crude oil production growth is expected to be light

and sweet (low sulfur) crude oils, but many U.S. refineries, such as those along the Gulf Coast, are optimized to process heavy, sour (high sulfur) crude oil grades.

In addition to configurational mismatches between production and refining, transportation constraints also will continue to cause refiners to rely on crude oil imports to meet refining capacity. For example, insufficient infrastructure exists to move sufficient crude oil production supply from the Gulf region to meet domestic refinery demand on the East and West Coasts.

The United States will continue to be a net exporter of coal and coke, but exports are not expected to increase because of competition from other global suppliers closer to major consuming markets.

Petroleum liquids production

U.S. crude oil and natural gas plant liquids production exceeds their peak 1970 levels; consumption of petroleum liquids remains lower than its 2004 peak level

The United States is now the largest producer of crude oil in the world. According to AEO2019 projections, U.S. crude oil production will continue to grow as upstream producers increase output because of rising prices and cost reductions.

U.S. crude oil production continues to set annual records, exceeding 14.0 million b/d in the mid-2020s and remaining higher than that level through 2040. The continued development of tight oil and shale gas resources, particularly those in the East and Southwest regions, supports growth in NGPL production. NGPL production, already at a record high, is projected to grow in the long term, exceeding 6.0 million b/d before 2030.

Petroleum product consumption is projected to remain mostly steady through the projection period, although projected consumption is sensitive to changes in assumptions regarding oil prices and economic growth.

As a result of increasing crude oil and other petroleum liquids production and relatively unchanged petroleum product consumption, the United States is projected to be a net exporter of petroleum on a volume basis from 2020 to 2049.

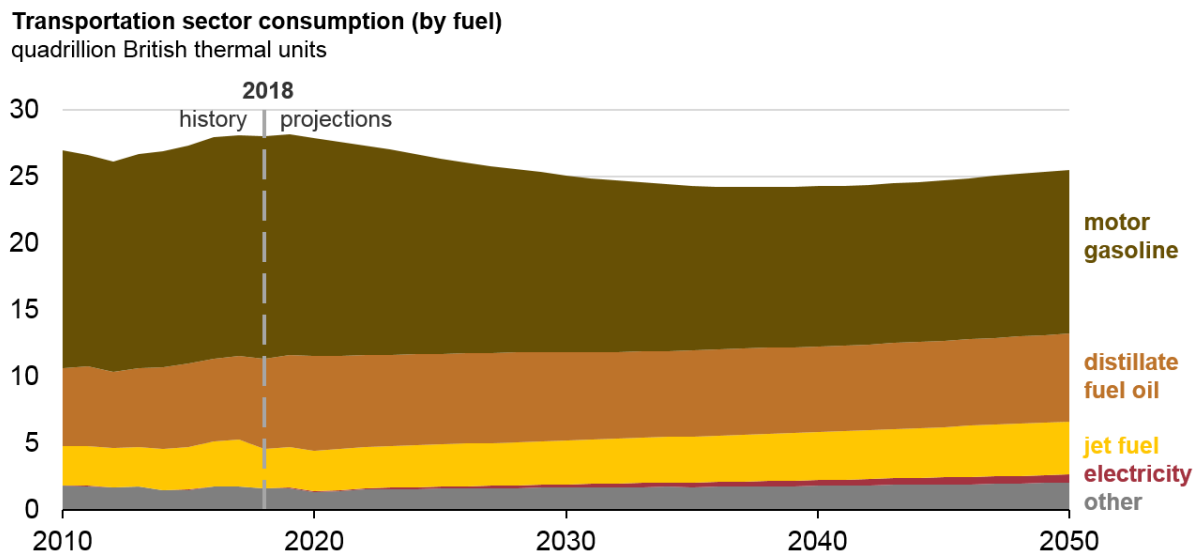

Petroleum liquids consumption

Transportation energy consumption generally declines between 2019 and 2037 as fuel economy increases offset growth in vehicle miles traveled

Figure 5 shows jet fuel energy consumption will grow more than any other transportation fuel during the projection period as increases in GDP lead to growth in air transportation that outpaces increases in aircraft fuel efficiency. Electricity use in the transportation sector starts from a relatively low base and continues to grow through 2050.

Motor gasoline and distillate fuel oil’s combined share of total transportation energy consumption decreases through 2050 as a result of gains in energy efficiency supported by current laws and regulation. However, assuming no further policy actions, increases in fuel economy standards are projected to reduce the total consumption of motor gasoline through the mid-2020s. The plateauing of mandated energy efficiency gains after 2027 and the increase in vehicle miles traveled (VMT) as the economy continues to grow, results in motor gasoline consumption increases in the second part of the projection period (Figure 6).

Figure 6. Transportation sector consumption declines through 2037

Natural gas

Natural gas production growth outpaces natural gas consumption growth

Domestic natural gas production increases through the projection period, driven by tight and shale natural gas production. The size of the associated resources and the improvements in technology allow for the development of tight and shale resources at lower costs. In particular, the eastern United States is projected to drive the growth in natural gas output, followed by production growth along the Gulf Coast. Dry natural gas production reaches 43.4 trillion cubic feet (Tcf) by 2050.

Growth in drilling in the Southwest region drives increases in natural gas production from tight oil formations. Because drilling activity in oil formations primarily depends on crude oil prices rather than on natural gas prices, the increase in natural gas production from oil-directed drilling puts downward pressure on natural gas prices.

Offshore natural gas production in the United States remains mostly unchanged during the projection period as production from new discoveries generally offset declines in legacy fields.

The projected growth in U.S. natural gas consumption, although significant, is not expected to keep pace with production growth, allowing net natural gas exports to continue to grow through 2050 (Figure 7). As additional LNG export terminals are constructed, growth in exports is projected to be led by waterborne trade, but LNG exports will remain highly sensitive to crude oil and natural gas prices.

Figure 7. Net exports of natural gas will continue to grow through 2050

Electric power

Electric power and industrial demand drive natural gas consumption

Continued, relatively low natural gas prices will lead to increasing use of natural gas across most end-use sectors. The industrial sector is projected to be the largest consumer of natural gas, as the chemical industry and industrial heat and power grow through the projection period.

Relatively low natural gas prices also lead to higher use of natural gas for electric power generation. Natural gas-powered generation is projected to grow through the projection period and remain the largest fuel by share in this sector through 2050 under current laws and regulations in the Reference case.

Additions to electric power generation will be met by natural gas and renewables

Generation from renewable electricity sources, including hydroelectricity, grows the most during the projection period. This growth is initially supported by various tax incentives that are scheduled to phase out through the 2020s. Without further policy incentives, renewable generation continues to grow, but at a slower rate, as capital costs to construct new generating capacity continue to decline.

Figure 8. Natural gas and renewables additions dominate

Although coal and nuclear continue to decrease in nearly all cases, these fuels will continue to play a role in the U.S. electricity generation mix through the projection period. Renewable electricity generation surpasses nuclear generation in about 2020 and surpasses coal in about 2025 (Figure 9).

Long-term trends in capacity additions for electricity generation are dominated by the addition of solar and natural gas capacity. Wind capacity additions are more modest, while less economically competitive coal, nuclear, and natural gas plants are expected to see capacity retirements. About 42% of coal-fired capacity and about 22% of current nuclear capacity is projected to retire by 2050.

Figure 9. Electric power generation mix sees a transformation in the medium term

Natural gas prices and policy incentives drive the growth in electricity generation fuel mix. In the AEO2019 Reference case, relatively low natural gas prices lead to natural gas-powered generation growing steadily and remaining the dominant fuel through 2050. However, because of the high sensitivity to natural gas prices, the AEO2019 also modeled a high natural gas price case where renewables are projected to become the leading source of electricity generation by 2030.

Carbon dioxide

Despite overall increases in energy consumption, carbon dioxide intensity declines across end-use sectors

Changes in the fuel mix primarily drive the lower carbon dioxide (CO₂) intensity, which can vary greatly depending on the mix of fuels consumed in each sector. For example, the generation fuel mix in the electric power sector now relies on less carbon-intensive sources, such as natural gas and renewables. In contrast, a decade ago, the electric power sector relied on coal as a feedstock. Given the projected trends in the electric power sector fuel mix, CO₂ emissions will continue to decrease through 2050.

In 2018, CO₂ emissions increased by 3% as a result of increased energy consumption. Consumption rose as a result of robust economic growth and unfavorable weather conditions. EIA projects that emissions will remain at least 2% lower than the 2020 level across the projection period. However, EIA projects that energy-related CO₂ emissions will initially decline through 2040 and then increase in the last decade of the projection period. This pattern primarily follows petroleum emissions. Petroleum emissions are projected to decline until 2040, but they will then rise as vehicle miles traveled increase and motor gasoline consumption begins to increase again toward the end of the projection period. The increase in gasoline consumption is a result of current regulations not requiring additional fuel efficiency increases after 2027. This projection is highly uncertain because many fuel efficiency standards are currently under discussion.

Natural gas CO₂ emissions are projected to increase through 2050, and coal-related CO₂ emissions are projected to decline as coal-fired electric power plants retire. The generation fuel mix in the electric power sector has changed significantly since the mid-2000s, with lower generation from high-carbon intensive coal and higher generation from natural gas and carbon-free renewables, such as wind and solar. This change resulted in the overall CO₂ intensity of the electric power sector declining by 25% from the mid-2000s to 2018 and continuing to decline through 2050. Electric power, however, can be considered in the context of each end-use sector, and Figure 10 shows CO₂ intensities with the electric power sector redistributed to each end-use sector. Carbon intensities are calculated as carbon dioxide emissions per unit energy output in British thermal units.

Figure 10. Carbon dioxide intensity by end-use sector

**Carbon dioxide intensity by end-use sector
(Reference case)**

metric tons of carbon dioxide per billion British thermal units

Note: Carbon dioxide intensities are calculated as carbon dioxide emissions per unit energy output (in British thermal units).

About EIA

The U.S. Energy Information Administration (EIA) was established by the Department of Energy Organization Act of 1977 as the primary federal government authority on energy statistics and analysis. EIA is one of the 13 principal federal statistical agencies and is responsible for collecting, analyzing, and disseminating relevant, accurate, and timely energy information to inform public and private decision making.

EIA neither formulates nor advocates policy conclusions; and, by law, its data, analyses, and forecasts are independent of approval by any other officer or employee of the United States Government. Therefore, EIA reports should not be construed as products of the U.S. Department of Energy or other federal agencies.

EIA Annual Energy Outlook (AEO) and Short-Term Energy Outlook (STEO)

EIA prepares short- and long-term energy outlooks. The *Short-Term Energy Outlook* (STEO) examines trends over the next one to two years. The *Annual Energy Outlook* (AEO) models projections over the long-term.

EIA’s AEO2019 was released on January 24, 2019. The AEO is the annual report on the long-term outlook for the energy system of the United States and provides data projections through 2050. Like all modeled projections and forecasts, the AEO2019 projections depend on input assumptions that are highly uncertain. However, the Reference case assumes current laws and

regulations remain unchanged during the projection period, which makes it useful as a baseline that can inform potential future policy discussions.

EIA's STEO is a monthly forecast covering the current and upcoming calendar year, and it provides monthly forecast data for supply, consumption, and prices across energy commodities. The STEO published January 15, 2019, is the first to include forecasts for 2020.

Conclusion

This is an exciting and transformational time for the United States energy industry as world energy markets adjust to the United States becoming a major global supplier and exporter for years to come.

Madam Chairwoman and Members of the Committee, thank you for the opportunity to present this information. This concludes my testimony.
